

Q: How does HILEVEL define “data” and “clock” rate?

“If you wish to converse with me, define your terms.” - Voltaire

For some tester manufacturers, the question of the “true” definition of data rates (or clock rates) has been an issue of “specmanship” more often than it has been of service to those seeking the “truth”. Since these variations can be frustrating, we at HiLevel would like to offer *our* definition of data and clock rates and try to help you understand how other views can vary.

What Happens in the ETS?

One of the most important points we wish to make clear is that the HiLevel basic program cycle is 20ns (i.e., 50MHz). This means that data is retrieved from RAM, formatted, processed and driven (as well as received in the case of DUT outputs) all within a *single program cycle*, including loops, branches and other programmed instructions. Not all testers do this; some employ muxing tricks, with the resulting idiosyncrasies. We put a great deal of effort into developing a custom chip specifically for the purpose of performing these operations in a single cycle.

Obviously a higher clock rate compels the need for better resolution. Pin-to-pin skew is equally important for insuring accuracy at higher speeds. At 500MHz, how meaningful is a 2ns cycle time if the edge placement resolution is no better than 100ps? The HiLevel ETS788 delay resolution is 50ps, allowing for excellent resolution in such situations. And where skew relationships are extremely critical, we provide the tools for manual deskew between pins in critical data paths.

Let us now look at some specifics regarding HiLevel Test Rate, and some discussion about other perceptions of test rates and clock rates.

Bidirectional Data

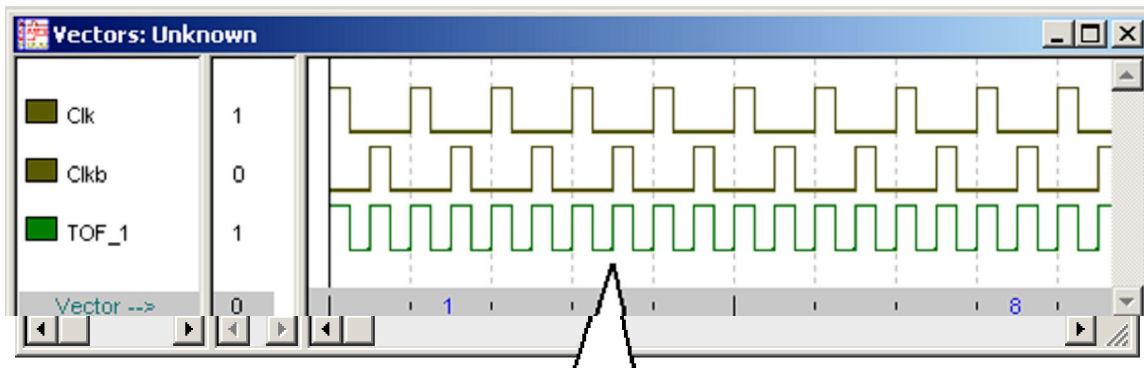

HiLevel 's classification of the basic data rate is somewhat simplistic; the “Test Rate” as defined in the Run Setup window reflects the bidirectional data rate. You can provide stimulus to the device at 2X the data rate (or the “Test Rate” as defined in the Run Setup window), but the *acquisition* of DUT output data is done at 1X -- in other words, at the defined Test Rate.

Stimulus Data

To achieve 2X stimulus data rate, the Timing On-the-Fly feature is employed (TOF). This feature is covered in the Presto manual and the online Help file that comes with your Presto software. Some additional system resources are consumed in this mode, but data rates of up to 110MHz are possible with TOF. See the example on the next page of how a 100MHz clock is created.

Other Views

Some users and tester manufactures define an edge transition as being the delimiter in determining actual test rate. In other words, if RZ or R1 data format is selected then *two* edge transitions are encountered during each test cycle and the perceived test rate is *double* that of the defined test rate. If this philosophy is employed, the ETS788 (a 55MHz test system) is capable of delivering a **110MHz** stimulus test rate, referring to the previous example. However, HiLevel prefers to retain the indisputable premise that the actual “Test Rate” is as defined in the Run Setup window. You may draw your own conclusions regarding views other than the conventional.

Clk and Clkb are logically OR'd to form the double-clocking seen in green. TOF_1 is the actual output data present on channel 1 for the DUT input pin. There are two pulses per vector, so with our test rate at 50MHz, this clock is 100MHz.

What Next?

Can HiLevel produce a system with test rates beyond 55MHz? Most certainly, we already have. We've already introduced the Griffin III and the Titan, capable of speeds of up to 200MHz. And you can use the Fast Clock Board to produce clocks up to 500MHz. Presently, our gate arrays can perform all system functions in real time -- everything is done on the fly with no tricky muxing. It's just a matter of making this (currently) six-micron architecture even faster. Of course, we will always offer an attractive upgrade path for HiLevel customers. And as always, your setup and vector files will be easily transportable from older to newer systems.
